

Towards final tests with new ACQ1002 modules

The DAQ team

“Duplicated(repeated) sample issue”

Per David’s suggestion to reduce low frequency noise looking at the distribution of the difference between consecutive (even/odd) pairs of ADC samples

Discovered that in each channel, from time to time, ADC samples are duplicated from previous, or even earlier samples. (Will explain in detail in the following slides)

First saw this in “synchronized trigger mode”, however the issue is observed in “continuous mode”.

The issue is independent of chosen frequency, FPGA averaging or ADC box

Perhaps it is indicative of memory issue at the readout stage in FPGA ?

“duplication issue” appears to be random so in principle shouldn’t introduce additional false asymmetry

DAQ test setup in CONTINUOUS mode

Single vs. “pair” ADC sample distributions: CONT, 50kHz, nacc=1

Single ADC (conv)
distribution for first 8
channels of box021:

- 1.) CONTINUOUS
- 2.) 50 kHz
- 3.) nacc=1 (No Averaging)

$A_{2j} - A_{2j-1}$: adjacent
pair difference
distribution for first 8
channels of box021:

- 1.) CONTINUOUS
- 2.) 50 kHz
- 3.) nacc=1 (No Averaging)

Raw datastream: Box021, CONT, 50kHz, No averaging

```

Printout of raw ADC DataStream
indeed confirms the existence of
“duplicate” adjacent samples

But “duplication” issue goes
beyond adjacent samples

Samples are often repeated after
Several

Single ADC sample distr. ALL vs. ONLY duplicated : CONT, 50kHz, nacc=1

Single ADC (conv)
distribution for first 8
channels of box021:

- 1.) CONTINUOUS
- 2.) 50 kHz
- 3.) nacc=1 (No Averaging)

Raw ADC samples ONLY
when “adjacent
duplication” occurs

The shape of upper and
lower distributions look
alike, which shows that
duplicated sample
values are random!

Pair distributions for testing data

“difference between ADC sample pairs” distributions:

$A_1, A_2, A_3, A_4, A_5, A_6, A_7, A_8, A_9, A_{10}, \dots$

- “adjacent pair diff” $(A_2-A_1), (A_4-A_3), (A_6-A_5), (A_8-A_7), (A_{10}-A_9), \dots$
- “NN pair diff” $(A_3-A_1), (A_4-A_2), (A_7-A_5), (A_8-A_6), (A_{11}-A_9), (A_{12}-A_{10}), \dots$
- “NNN pair diff” $(A_4-A_1), (A_5-A_2), (A_6-A_3), (A_{10}-A_7), (A_{11}-A_8), (A_{12}-A_9), \dots$
- “NNNN pair diff” $(A_5-A_1), (A_6-A_2), (A_7-A_3), (A_8-A_4), (A_{11}-A_8), \dots$

Adjacent and beyond “pair” ADC sample distributions: CONT, 50kHz, nacc=1

The effect is still there for Next-to-Next-to-Next-to-Next pair difference distributions

How about when we FPGA Average data? CONT, 50kHz, nacc=16

Single ADC (conv)
distribution for first 8
channels of box021:

- 1.) CONTINUOUS
- 2.) 50 kHz
- 3.) nacc=16

Duplication issue still
there from pair
distributions when we
FPGA average

But width of the
distributions varying,
which wasn't the case
for Non-Averaged
case!

Let's change sampling rate? CONT, 32kHz, nacc=1

Single ADC (conv)
distribution for first 8
channels of box021:

- 1.) CONTINUOUS
- 2.) 32 kHz
- 3.) nacc=1

Same effect!

“duplication” doesn't
depend on sampling
rate

Conclusions

I quickly checked data with “old” ACQ2006 box and the issue is there as well.

The duplication doesn't depend on running mode, sampling rate, box

Vince suggested that this might be a FIFO memory issue at the readout. But this is really Peter's job to determine

Very next step is to check this thing with input signal. Sinusoidal, Slope, etc.

Other quick tests.

But looks like the issue is random.

Backup slides

Raw datastream: Box021, CONT, 50kHz, ave coef = 16
