1-d. Average of Uniform Deviates—By the *Central Limit Theorem* (CLT), the average  $\bar{x}$  of n samples from a random variable X with almost any distribution tends to the Gaussian distribution as  $n \to \infty$ .

**a)** Calculate the mean  $\mu$  and standard deviation  $\sigma$  of the *uniform* random variable X with probability distribution  $p_u(x) = 1$  if 0 < x < 1 and 0 otherwise.

**b)** Histogram the distribution of 100,000 averages of n = 1, 2, 3, 5, 10, and 100 uniform deviates each. Calculate the mean  $\langle \bar{x} \rangle$  and standard deviation  $s_{\bar{x}}$  of each sample distribution, and compare with  $\mu_{\bar{x}} = \mu$ ,  $\sigma_{\bar{x}} = \sigma/\sqrt{n}$  from the parent distribution. Plot the Gaussian distribution function  $p_G(\bar{x}; \mu_{\bar{x}}, \sigma_{\bar{x}})$  together with each histogram.

c) Calculate  $p_{\chi}(u; 1)$  for the  $\chi^2$  distribution with  $\nu = 1$  degree of freedom by using the *invariant*  $p_{\chi}(u; 1)du = 2p_G(z)dz$ , where  $u = \chi^2 = z^2$ . The factor of two comes from combining the left and right tails.

**d)** For n = 100, histogram  $u = z^2$ , where  $z = (\bar{x} - \mu)/(\sigma/\sqrt{n})$ , and plot together with the  $\chi^2$  distribution  $p_{\chi}(u; 1)$  with  $\nu = 1$  degree of freedom.

**2-d. Gaussian Generator**—The  $\chi^2$  distribution with  $\nu = 2$  degrees of freedom can be used to create a more efficient and accurate Gaussian generator.

a) Integrate joint Gaussian distribution  $p(\vec{\chi}) = p_G(z_1)p_G(z_2)$  of the vector  $\vec{\chi} = (z_1, z_2) = (\chi \cos \phi, \chi \sin \phi)$  over  $\phi$  in cylindrical coordinates  $(\chi, \phi)$  to obtain the  $\chi^2$  distribution  $p_{\chi}(u; 2)$  where  $u = \chi^2 = \vec{\chi} \cdot \vec{\chi} = z_1^2 + z_2^2$ .

**b)** Histogram the distribution of  $u = z_1^2 + z_2^2$  into 1000 bins over  $0 \le u \le 10$ , using 100,000 pairs  $(z_1, z_2)$  from 1b) with n = 100 again, and plot together with  $p_{\chi}(u; 2)$  from 2a).

c) Working backwards, use the fact that  $p_u(x)dx = p_e(u)du$  to determine the function u(x) which transforms the uniform deviate x into u following the exponential distribution  $p_e(u) = \frac{1}{2} \exp(-u/2)$  defined on  $0 \le u < \infty$ .

d) Generate a 100,000 pairs of Gaussian deviates  $\vec{\chi} = (z_1, z_2)$  by generating  $\chi = \sqrt{u}$  from the exponential deviate u of 2c) and a uniform deviate  $\phi$  in the range  $0 \le \phi < 2\pi$ , and finally transforming  $(\chi, \phi)$  back to rectangular coordinates  $(z_1, z_2)$ . Histogram both z's in 1000 bins over  $-5 \le z < 5$  and plot each together with the normalized Gaussian distribution. **3-d.** [bonus: The Maxwell distribution of the energy of atoms in an ideal gas is just the  $\chi^2$  distribution for  $\nu = 3$  degrees of freedom because each component of  $\vec{v} = (v_x, v_y, v_z)$  is normally distributed accoring to its Boltzmann factor  $p_B(v_x) = e^{-E/kT}$ , where  $E = v_x^2/2m$ , etc.

a) Integrate the 3-d velocity distribution over spherical shells of thickness dv to derive the Maxwell distribution of velocities  $p_M(v)$ . Use the Gaussian generator of 2d) to generate 100,000 velocities in units of  $\sqrt{mkT}$  and histogram them together with a plot of  $p_M(v)$ . Calculate the mode  $v_{max}$ , median  $v_{1/2}$  mean  $\bar{v}$ , and RMS  $v_{rms} = \sqrt{\langle v^2 \rangle}$ .

**b)** Integrate the joint normal distribution  $p(\vec{\chi}) = p_G(z_1)p_G(z_2)p_G(z_2)$  over spherical shells of radius du for  $u = \vec{\chi} \cdot \vec{\chi}$  in the vector space  $\vec{\chi} = (z_1, z_2, z_3)$  to obtain  $p_{\chi}(u; 3)$ . Show that the Maxwell energy distribution equals  $p_{\chi}(v^2/mkT; 3)$ .

. . .

*n*-d. [bonus: Higher dimensional  $\chi^2$  distributions are used to test the consistency of distributions, as in labs X03 and X04, or fit functions. In this case  $\nu$  equals the number of Gaussian distributions (for example, the bins you are comparing) minus the number of constraints (for example, the parameters of a distribution or fit function).

a) Using the volume of a  $\nu$ -dimensional ball  $V_{\nu}(\chi) = \pi^{n/2} \chi^n / \Gamma(n/2+1)$ , integrate the  $\nu$ -d joint Gaussian distribution over hypershells to derive the  $\chi^2$  distribution  $p_{\chi}(u;\nu)$ . Plot the distribution for  $\nu = 1, 2, 3, ..., 10$ .

**b)** Show that as  $\nu \to \infty$ ,  $p_{\chi}(u;\nu)$  tends to the Gaussian distribution  $p_G(u;\nu;2\nu)$ .
